EXAMINATION BOOK

NAME

MIJARES, ANTHONY S.

DATE

02-27-2026

INSTRUCTOR

DR. RODOLFO RAGA

SUBJECT

ITC CSOG - 301i

DO NOT TEAR ANY PAGE OUT OF THIS
EXAMINATION BOOK

Test 1

2. Upon observing the scatterplot, the strength of the relationship between the two attributes, namely Advertising Spend, and Product Sales are leaning towards the stronger positive. In addition, given that we need to have a rough estimate it will be a value closer to ± 1 as the regression line is showcasing based on the trend. The higher the budget, the better the sales for advertising.

3. ~~(The)~~ Upon assessing the correlation between the predictor, which is the ~~(Product Sales)~~, and ~~(the)~~ Advertising Spend

Upon assessing the correlation between the predictor, which is the Advertising Spend, and the target attribute, Product Sales, it clearly indicates that it is strong enough to forecast

store sales figures, as by looking
on the individual records you can
predict that the more ~~target~~ budget
you spend on advertising can yield
a higher product sales!

Test II

1. a.) From what I learn from the previous tests, the intercept value is the 0.13 and in regards to having a 0 value as a predictor may always return a value of 20 by just computing using the formula. Although, to me it is an error as 0 value as a predictor can cause issues on the algorithm hence, ensuring that you implement clipping through the minimum value can help.

b.) The slope value is 20 and will be added to the Advertising Spend amount multiplied by the intercept.

2.) Since the model returns a value of 0.98 or 98%, this may give an impression that the predictor can seem perfectly accurate aid in predicting the total sales. Hence it clearly indicates that the more budget allotted to the Advertising can return better sales figure

a) The main reason why it is theoretically impossible for a real-world predictive model to have an accuracy of a perfect 100% is due to the fact that real-world data is noisy, bias and inconsistent in nature. In addition it also have outliers, in which may result in lowering the accuracy of a predictive model, as garbage in, garbage out concept implied. Ultimately, apply data cleaning and preparation procedure can aid the model in providing acceptable prediction to aid in data-driven decision-making.
